

Hybrid Network Architecture for Greenhouse (Produce Growing Company)

Fog Layer

Employees

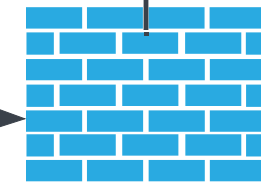

Smart Edge Router

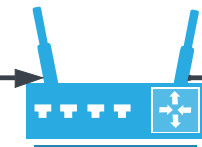

IoT / Diagnostic
Devices

Management of the greenhouse's systems lives here. Monitoring devices, hydration and humidity management, and soil sample analysis tech are all IoT devices connected to the company's data structure at this fog layer. Additionally, as employees and the aforementioned tech need to be mobile within the greenhouse, standard employee network connection is also managed at this layer.

Centralized Layer

Firewall

Core Router

Storage
Server

Central
Network
Controller

Cloud storage is expensive! This greenhouse has decided to store and analyze all its growing data locally, since only a small portion of it is kept year-over-year. As that data is considered company-sensitive, it is protected by a more extensive firewall. While most of the company's day-to-day operations are centralized, it does not have a local authentication database.

Cloud Layer

Cloud Services

Cloud
Authentication
Server

To allow the local server infrastructure to be data-focused and analysis-optimized, this greenhouse has outsourced their identity management and authentication to a cloud service like Azure. IT teams can add and configure devices on the fly, as well as manage user permissions with ease.
